The square in this picture is a "window" where you input the numbers. Note that there may be more than one "window". For example,

$$\boxed{\frac{4\square^2-1}{|\square|+1}}$$

Reader: Obviously, the function you have in mind is $\boxed{y=\frac{4x^2-1}{|x|+1}}$

Author: Sure. In this case each specific value should be input into both "windows" simultaneously.

- By the way, it is always important to see such a "window" (or "windows") in a formula describing the function. Assume, for example, that one needs to pass from a function $y=f(x)$ to a function $y=f(x-1)$ (on a graph of a function this transition corresponds to a displacement of the curve in the positive dir of the x-axis by 1).
- If you clearly understand the role of such a "window" ("windows"), you will simply replace in this "window" (these "windows") x by $(x-1)$. Such an operati on is illustrated by Fig 11 which represents the following function

$$\boxed{y=\frac{4x^2-1}{|x|+1}}$$

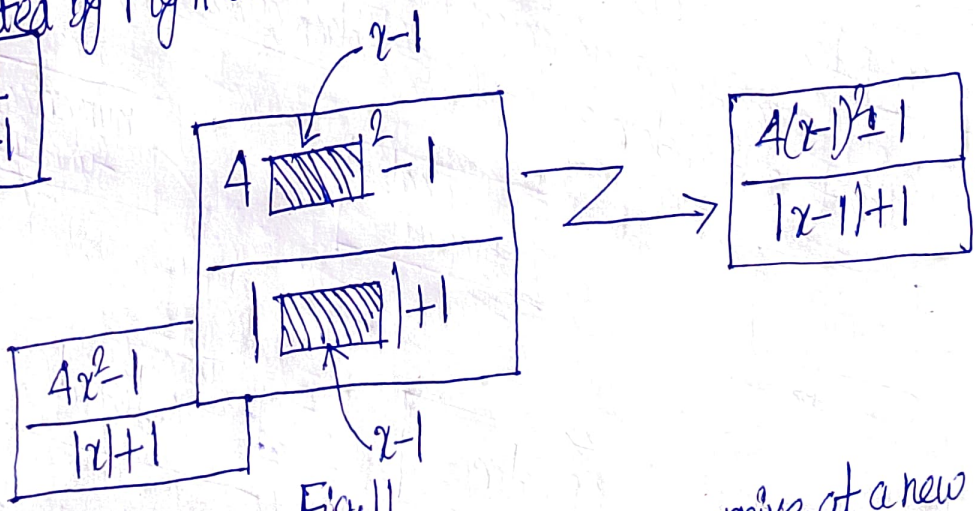

Fig. 11

Obviously, as a result of substitution of $(x-1)$ for x we arrive at a new function (new "black box")

$$\frac{4(\square-1)^2-1}{|\square-1|+1} \qquad \boxed{y=\frac{4(x-1)^2-1}{|x-1|+1}}$$
